Common Carp

Scan for more information

Species Description

Scientific name: Cyprinus carpio

AKA: Bred forms; Mirror carp, Leather carp, Koi carp,

Linear carp

Native to: Eastern Europe and Asia

Habitat: Rivers, streams, lakes and ponds; tolerates wide range of freshwater conditions, prefers slow or

stagnant water with muddy bottom and thick

vegetation.

Many forms of carp have been bred and as a result they are highly variable in appearance. Common carp have brown-green back and upper sides, silvery to golden-brown flanks and a white belly. It is usually $25-75\,\mathrm{cm}$ (can grow up to 100cm) in length and weights up to 30kg. It has a thick to round body and large protruding lips with 2 long and 2 short barbels originating from the upper jaw. The dorsal fin is concave with a long base and strongly serrated spine at the front.

C. carpio is an omnivorous bottom-feeder, it is most active at dusk and dawn and forms small shoals in spring. As a water temperature of over 18°C is required for reproduction, spawning occurs in June – July, however this temperature is rarely recorded in Northern Ireland. If conditions are suitable for spawning, energetic splashing can be observed around dusk in water body margins.

In waters where common carp does become established they alter the habitat by consuming plants and invertebrates and also by increasing turbidity.

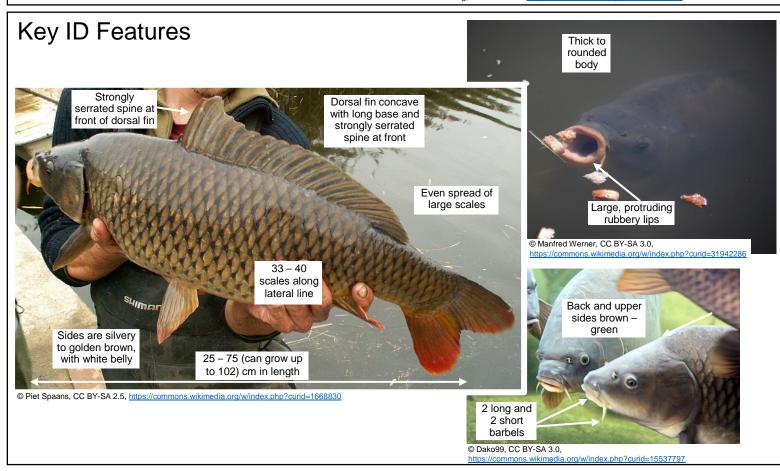

Some other forms of carp which have been selectively bred include; Mirror carp, which has irregular rows of large mirror–like scales. Leather (or naked) carp, almost devoid of scales. Line carp, which has a single lateral line row of scales. Koi carp (ornamental carp) which are highly coloured. There are also many variants within each of these froms.
